ability to quantify progress toward targets (23). The benefits of maintaining biodiversity are well known (24). Our results provide a baseline against which to measure progress toward this objective in 2020 and suggest that efforts need to be redoubled to positively affect trajectories of change and enable global biodiversity goals to be met by the end of the current decade.

CELL-FREE ASSAYS
Spatial organization of cytokinesis signaling reconstituted in a cell-free system

Phuong A. Nguyen,1,2‡ Aaron C. Groen,1,2‡ Martin Loose,1 Keisuke Ishihara,1,2 Martin Wühr,1 Christine M. Field,1,2‡ Timothy J. Mitchison1,2‡

During animal cell division, the cleavage furrow is positioned by microtubules that signal to the actin cortex at the cell midplane. We developed a cell-free system to recapitulate cytokinesis signaling using cytoplasmic extract from Xenopus eggs. Microtubules grew out as asters from artificial centrosomes and met to organize antiparallel overlap zones. These zones blocked the interpenetration of neighboring asters and recruited cytokinesis midzone proteins, including the chromosomal passenger complex (CPC) and centralspindlin. The CPC was transported to overlap zones, which required two motor proteins, Kif4A and a Kif20A paralog. Using supported lipid bilayers to mimic the plasma membrane, we observed the recruitment of cleavage furrow markers, including an active RhoA reporter, at microtubule overlaps. This system opens further approaches to understanding the biophysics of cytokinesis signaling.

A
tomyosin-based cleavage furrows in animal cells are positioned by signals emanating from microtubule astrobilam formed shortly after anaphase onset (1). In typical somatic cells, the signaling complexes centralspindlin and the chromosomal passenger complex (CPC) accumulate at the center of the midzone (or central spindle), which forms in the space previously occupied by the mitotic spindle (2). It is unclear how the microtubules that position furrows are organized in much larger egg cells and how they signal to the cortex. We addressed these questions by developing a cell-free system to reconstitute the spatial signaling that is characteristic of cytokinesis in a large egg cell.

To reconstitute cytokinesis events, undiluted egg cytoplasm with intact actin (3), containing fluorescent probes and Aurora kinase A (AurkA)–based artificial centrosomes beads (4), was treated with Ca2+ to mimic fertilization and immediately spread between two coveslips for imaging (fig. S1A). As the cell cycle progressed from metaphase to interphase (5), large microtubule asters grew out rapidly from each AurkA bead. Where the expanding edges of two neighboring asters met, antiparallel microtubule bundles formed in a boundary zone that we term the aster-aster interaction zone (AAIZ) (Fig. 1, A to C, and movie S1). In somatic cells, the CPC and centralspindlin complexes are recruited to the midplane in anaphase, where they specify the division plane by activating the small GTPase RhoA (2). We imaged endogenous complexes by adding labeled antibodies, and for the CPC we confirmed localization with a green fluorescent protein (GFP)–tagged DasrA subunit (5). CPC and the Kif23 subunit of central-

Kif11 (Eg5), Kif20A (Mklp2/Rabkinesin-6), and Kif23 (Mklp1, a subunit of centralspindlin). Xenopus eggs also contain an unusual kinesin 41% identical to Kif20A by sequence (11). This is likely to be an embryo-specific paralog, and we propose the name Kif20A embryonic, abbreviated KIF20AE. Small-molecule inhibition of Kif10 and Kif11, and depletion of somatic Kif20A and Kif23, had no effect on antiparallel microtubule bundling in the AAIZ or on CPC localization (Fig. 2, A and B, and figs. S5 and S6). Depletion of Kif4A did not block CPC accumulation or the assembly of antiparallel bundles, but increased the width of the CPC-positive zone; adding back recombinant Kif4A rescued this phenotype (Fig. 2A and fig. S6). Depletion of Kif20AE completely blocked CPC accumulation and disorganized the AAIZ (Fig. 2A). Thus, Kif20AE is absolutely required for CPC recruitment in eggs, presumably mirroring the Kif20A requirement in somatic cells (9), and Kif4A plays some role in focusing it. Microtubule bundles in the AAIZ localized Kif20AE (Fig. 2C), Kif4A (Fig. 2D), and an embryonic paralog of PRC1 (PRC1E, an antiparallel microtubule crosslinker; fig. S1D), all of which have been shown to bind the CPC in pull-down experiments (9, 12–14). Time-lapse imaging showed that CPC clusters moved to the center of the overlap zone at a rate of 10 to 25 μm/min, slowing as they reached the center (Fig. 2, E and F, fig. S7, and movie S4). Tubulin speckle imaging showed sliding of microtubules away from the overlap center at <5 μm/min (fig. S8 and movies S6 to S8). Thus, the observed CPC movement represents transport toward plus ends. The maximal transport rate was close to that of Kif4A in an isolated aster that was not part of an AAIZ (Fig. 2F, green line, and fig. S9) (5). Kif4A depletion blocked CPC movement, and addback of recombinant Kif4A rescued it (Fig. 2, E and F, fig. S10, and movie S5). Live imaging showed partial colocalization of CPC and Kif4A movement (fig. S11). Thus, the CPC is targeted to the AAIZ and transported to a narrow band by the combined action of Kif20AE and Kif4A. Transport probably slows as CPC engages binding sites in the AAIZ (5).

To test whether AAIZs in the cell-free system can signal to the cortex, we prepared supported lipid bilayers on glass coverslips, using lipids characteristic of the inner leaflet of animal cell plasma membranes, including phosphatidylinositol (PI) and phosphatidylinositol 4,5-bisphosphate [PI(4,5)P2] (5, 15). Protein recruitment was imaged...
using total internal reflection fluorescence (TIRF) microscopy (Fig. 3A). The small GTPase RhoA is thought to be the master organizer of the furrow (16). To localize active, GTP-bound RhoA we added an mCherry-tagged RhoA binding fragment of Rhotekin (mCherry-rGBD) (16). Using polyethylene glycol (PEG)–passivated coverslips, we saw no recruitment of RhoA-GTP. Using lipid bilayers, the RhoA-GTP reporter was enriched at the bilayer under AAIZs that recruited CPC and centralspindlin (Fig. 3B and fig. S12). Inhibition of AurkB or depletion of Kif20AE completely blocked AAIZ assembly and CPC localization as expected (8, 9) and also blocked localized RhoA-GTP enrichment (Fig. 3, B and C). Kif4A depletion resulted in the broadening of both CPC and RhoA-GTP zones (Fig. 3C). Depletion of Kif23, a subunit of the centralspindlin complex, did not block AAIZ assembly or RhoA-GTP recruitment (Fig. 3C). Centralspindlin plays a central role in midzone assembly and signaling in many biological systems (2). Its dispensability in our system probably reflects functional redundancy among midzone factors and is consistent with its dispensability.
in Xenopus blastomere cytokinesis (17). We conclude that a CPC-positive AAIZ can locally activate RhoA in our system, although we cannot distinguish whether localized AurkB phosphorylation of cytokinetic factors or some specific organization of microtubules at the AAIZ is required for furrow signaling.

To probe cortical organization in our system, we visualized F-actin using Lifeact-GFP (Fig. 4) (18). F-actin was enriched at the lipid bilayer under AAIZs (Fig. 4, A and B). Above the cortical layer, F-actin organized into branched networks that showed only partial alignment with the microtubules (Fig. 4C). At the cortical layer, F-actin organized into long, uniformly spaced cables that aligned radially with microtubules (Fig. 4D, left and middle, and movie S9). The spacing between actin cables was 1.3 ± 0.5 μm (SD; n = 140), comparable to the spacing of actin-containing contractile bands on the cortex of live frog eggs (19). This organization was microtubule-dependent (Fig. 4D, right); we suspect it represents a configuration of actin bundles that normally precedes furrow formation, because it has been noted in early anaphase in several systems (5). The furrow-selective actin bundling protein Anillin (20) colocalized with F-actin cables throughout the cortex and was enriched under AAIZs along with its binding partner septin complex (Fig. 4, C and E, and movie S10).

Summarizing, we have developed a cell-free system that recapitulates the hallmarks of spatially organized signaling characteristic of egg cytokinesis. Midzone proteins were recruited to the overlap zone between microtubule asters in egg extract, where they signaled to a nearby lipid bilayer to locally activate the RhoA pathway. Our system confirmed known mechanisms of spatially organized signaling (for example the AurkB activity requirement for cleavage furrow induction) and revealed new mechanistic aspects that were difficult to observe in living cells, notably transport of the CPC along microtubules toward the midzone in a process requiring two kinesins. Our data favor a model in which Kif4A is a transport motor for the CPC, and Kif20AE is required for it to bind microtubules, though not necessarily as a transporter. Future pure protein reconstitution experiments are required to conclusively determine the mechanism of CPC transport and the exact roles of these two kinesins.

Two factors facilitated imaging approaches in the cell-free system: the large spatial scale of the AAIZ (~30 μm) and its long time duration (>20 min). Both reflect the pre-cytokinesis organization of the large egg cell. In comparison, the microtubule overlap in somatic cell midzones is ~2 to 3 μm wide and lasts only ~3 min before being compressed by the furrow (21). Future studies will take advantage of these features and the experimental flexibility of an extract system to probe biophysical mechanisms involved in cytokinesis.
